**Physical Rehabilitation of Paralysed Facial Muscles: Functional and Morphological Correlates** Doychin N. Angelov,2011-02-21 Using a combined morpho functional approach the author

recently found that polyinnervation of the neuro muscular junction NMJ is the critical factor for recovery of function after transection and suture of the facial nerve Since polyinnervation is activity dependent and can be manipulated he tried to design a clinically feasible therapy by electrical stimulation or by soft tissue massage First electrical stimulation was applied to the transected facial nerve or to paralysed facial muscles Both procedures did not improve vibrissal motor performance video based motion analysis of whisking failed to diminish polyinnervation and even reduced the number of innervated NMJ to one fifth of normal values In contrast gentle stroking of the paralysed vibrissal muscles by hand resulted in full recovery of whisking Manual stimulation was also effective after hypoglossal facial anastomosis and after interpositional nerve grafting The author concludes that manual stimulation is a non invasive procedure with immediate potential for clinical rehabilitation following facial nerve reconstruction

**The Testicular Descent in Human** K.J. Barteczko,M.I. Jacob,2000-07-26 The testicular descent descensus testis is described in a complete series of human material from stage 14 CC to the adult state by using own phases Central points of interest in this work are answers to questions which have been discussed controversially by generations of scientists and which are wrong or inadequately documented in most textbooks of embryology Does an inner gonadal descent exist What about origin role and fate of gubernaculum H processus vaginalis peritonei and gonadal ligaments How do the annexes of testis come into their final position The results are based on serial sections scanning electron microscopy three dimensional reconstructions microdissection and immunohistochemistry

*Sperm Acrosome Biogenesis and Function During Fertilization* Mariano G. Buffone,2016-05-27 Over the last decades acrosomal exocytosis also called the acrosome reaction has been recognized as playing an essential role in fertilization Secretion of this granule is an absolute requirement for physiological fertilization In recent years the study of mammalian acrosomal exocytosis has yielded some major advances that challenge the long held general paradigms in the field Principally the idea that sperm must be acrosome intact to bind to the zona pellucida of unfertilized eggs based largely on in vitro fertilization studies of mouse oocytes denuded of the cumulus oophorus has been overturned by experiments using state of the art imaging of cumulus intact oocytes and fertilization experiments where eggs were reinseminated by acrosome reacted sperm recovered from the perivitelline space of zygotes From a molecular point of view acrosome exocytosis is a synchronized and tightly regulated process mediated by molecular mechanisms that are homologous to those reported in neuroendocrinal cell secretions The authors provide a broader perspective focusing on a limited number of important topics that are essential for understanding the molecular mechanisms governing this step in the fertilization process They also discuss molecular aspects such as the signaling pathways leading to exocytosis including the participation of ion channels lipids the fusion machinery proteins and the actin cytoskeleton as well as cellular aspects such as the site of acrosomal exocytosis and the use of gene manipulated animals to study this process

## **Electric Field-Induced Effects on Neuronal Cell Biology Accompanying Dielectrophoretic Trapping** Tjitske

Heida, 2003-06-23 1 1 Neuro Electronic Interfacing 1 1 1 Nervous System Communication in the human body and the interaction with the environment is controlled by the nervous system. It can be divided into a central part which includes the spinal cord, brainstem, cerebellum, and cerebrum, and a peripheral part which includes all neuronal tissue outside the central part (Martini, 2001). The latter provides the interface between the central nervous system and the internal and external environment of the body. Eye, ear, skin, and muscle sensors provide the necessary information. Via primary afferent neurons, this information is transmitted to the central nervous system. Conversely, this system provides information to the target organs via the efferent fibers. Furthermore, the central nervous system is responsible for cognition, learning, and memory. Neurons are cells specialized for receiving information and transmitting signals to other neurons or to effector cells such as muscles and glands (Levitan, 1991). Like all other cells, neurons are enclosed by a cell membrane which is a double layer of phospholipid molecules. This bilayer, about 10 nm thick, serves as a barrier that allows the cell to maintain an internal cytoplasmic composition far different from the composition of the extracellular fluid. It contains enzymes, receptors, and antigens that play central roles in the interaction of the cell with other cells.
